(57) **ABSTRACT**

In general, in one aspect, the invention relates to a system to
create vapor for generating electric power. The system
includes a vessel comprising a fluid and a complex and a
turbine. The vessel of the system is configured to concen-
trate EM radiation received from an EM radiation source.
The vessel of the system is further configured to apply the
EM radiation to the complex, where the complex absorbs the
EM radiation to generate heat. The vessel of the system is
also configured to transform, using the heat generated by the
complex, the fluid to vapor. The vessel of the system is
further configured to sending the vapor to a turbine. The
turbine of the system is configured to receive, from the
vessel, the vapor used to generate the electric power.

**ELECTRICITY GENERATION USING
ELECTROMAGNETIC RADIATION****CROSS-REFERENCE TO RELATED
APPLICATIONS**

This application claims priority pursuant to 35 U.S.C. §119(e) to U.S. Provisional Patent Application No. 61/286,617 entitled "Steam Generation Using Electromagnetic Radiation-Absorbing Nanoshells," filed Dec. 15, 2009 in the names of Nancy J. Halas, Peter Nordlander, and Oara Neumann, the disclosure of which is incorporated by reference herein in its entirety.

**STATEMENT REGARDING FEDERALLY
SPONSORED RESEARCH OR DEVELOPMENT**

The invention was made with government support under grant number AC52-06NA25396 awarded by the Department of Energy. The government has certain rights in the invention.

BACKGROUND

The generation of electricity generally involves harnessing energy and using that energy to operate a generator. At times, the energy used to operate the generator is created using a combustion process. For example, natural gas, coal, fuel oil, certain types of biomass, or some other suitable fuel may be combusted to generate heat. The combustion of the fuel may occur in a boiler, where the resulting heat is combined with fluid (commonly water) to generate vapor (commonly steam). Once the vapor reaches a certain temperature, the vapor may be channeled through a turbine to generate electricity. For example, as the vapor passes through the turbine blades, the turbine blades turn, which may cause the generator to rotate using a shaft.

SUMMARY

In general, in one aspect, the invention relates to a system to create vapor for generating electric power. The system includes a vessel comprising a fluid and a complex and a turbine. The vessel of the system is configured to concentrate EM radiation received from an EM radiation source. The vessel of the system is further configured to apply the EM radiation to the complex, where the complex absorbs the EM radiation to generate heat. The vessel of the system is also configured to transform, using the heat generated by the complex, the fluid to vapor. The vessel of the system is further configured to sending the vapor to a turbine. The turbine of the system is configured to receive, from the vessel, the vapor used to generate the electric power.

In general, in one aspect, the invention relates to a method to create vapor for generating electric power. The method involves applying EM radiation to a vessel comprising a fluid and a complex, where the complex absorbs the EM radiation to generate heat. The method further involves transforming, using the heat generated by the complex, the fluid to vapor. The method also involves sending the vapor from the vessel to a turbine to generate the electric power.

In general, in one aspect, the invention relates to an aggregate. The aggregate includes a first complex, where the first complex absorbs electromagnetic (EM) radiation over a first range of wavelengths. The aggregate further includes a second complex, where the second complex absorbs EM

2

radiation over a second range of wavelengths, where the first range and the second range partially overlap.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 shows a schematic of a complex in accordance with one or more embodiments of the invention.

FIG. 2 shows a flow chart in accordance with one or more embodiments of the invention.

FIG. 3 shows a chart of the absorbance in accordance with one or more embodiments of the invention.

FIGS. 4A-4B show charts of an energy dispersive x-ray spectroscopy (EDS) measurement in accordance with one or more embodiments of the invention.

FIG. 5 shows a chart of the absorbance in accordance with one or more embodiments of the invention.

FIG. 6 shows a chart of an EDS measurement in accordance with one or more embodiments of the invention.

FIG. 7 shows a chart of the absorbance in accordance with one or more embodiments of the invention.

FIG. 8 shows a flow chart in accordance with one or more embodiments of the invention.

FIG. 9 shows a chart of the absorbance in accordance with one or more embodiments of the invention.

FIG. 10 shows a chart of an EDS measurement in accordance with one or more embodiments of the invention.

FIGS. 11A-11C show charts of the porosity of gold corral structures in accordance with one or more embodiments of the invention.

FIGS. 12A-12C show charts of the mass loss of water into steam in accordance with one or more embodiments of the invention.

FIGS. 13A-13B show charts of the energy capture efficiency in accordance with one or more embodiments of the invention.

FIG. 14 shows a system in accordance with one or more embodiments of the invention.

FIG. 15 shows a flowchart for a method of creating vapor for generating electric power in accordance with one or more embodiments of the invention.

FIG. 16 shows a single line diagram of an example system for creating vapor for generating electric power in accordance with one or more embodiments of the invention.

FIGS. 17A and 17B show examples of a vessel including a complex and a fluid in accordance with one or more embodiments of the invention.

FIGS. 18A and 18B show examples of a vessel containing a complex in accordance with one or more embodiments of the invention.

FIG. 19 shows a single line diagram of an example system for creating vapor for generating electric power in accordance with one or more embodiments of the invention.

DETAILED DESCRIPTION

Specific embodiments of the invention will now be described in detail with reference to the accompanying figures. Like elements in the various figures are denoted by like reference numerals for consistency.

In the following detailed description of embodiments of the invention, numerous specific details are set forth in order to provide a more thorough understanding of the invention. However, it will be apparent to one of ordinary skill in the art that the invention may be practiced without these specific details. In other instances, well-known features have not been described in detail to avoid unnecessarily complicating the description.

In general, embodiments of the invention provide for generating electric power using an electromagnetic (EM) radiation-absorbing complex. More specifically, one or more embodiments of the invention provide for creating a vapor (e.g., steam) from a fluid (e.g., water) by heating the fluid using one or more complexes (e.g., nanoshells) that have absorbed EM radiation. The invention may provide for a complex mixed in a liquid solution, used to coat a wall of a vessel, integrated with a material of which a vessel is made, and/or otherwise suitably integrated with a vessel used to apply EM radiation to the complex. All the piping and associated fittings, pumps, valves, gauges, and other equipment described, used, or contemplated herein, either actually or as one of ordinary skill in the art would conceive, are made of materials resistant to the heat and/or chemicals transported, transformed, pressurized, created, or otherwise handled within those materials.

A source of EM radiation may be any source capable of emitting energy at one or more wavelengths. For example, EM radiation may be any source that emits radiation in the ultraviolet, visible, and infrared regions of the electromagnetic spectrum. A source of EM radiation may be manmade or occur naturally. Examples of a source of EM radiation may include, but are not limited to, the sun, waste heat from an industrial process, and a light bulb. One or more concentrators may be used to intensify and/or concentrate the energy emitted by a source of EM radiation. Examples of a concentrator include, but are not limited to, lens(es), a parabolic trough(s), mirror(s), black paint, or any combination thereof.

Embodiments of this invention may be used in any residential, commercial, and/or industrial application where electricity generation may be required, particularly large amounts of electricity generation. Examples of such applications include, but are not limited to, an electric power plant, processing and manufacturing for a number of market sectors (e.g., food processing and packaging, pulp and paper, printing, chemicals and allied products, rubber, plastics, cosmetics, textile production, electronics), hospitals, universities, steel mills and other factories in the metal industry, drug manufacturing, wastewater and sewage treatment, beverages, incineration, natural gas processing, and petroleum refining.

In one or more embodiments, the complex may include one or more nanoparticle structures including, but not limited to, nanoshells, coated nanoshells, metal colloids, nanorods, branched or coral structures, and/or carbon moieties. In one or more embodiments of the invention, carbon moieties include carbon nanostructures, including but not limited to carbon nanotubes, carbon film, or C-60 molecules. In one or more embodiments, the complex may include a mixture of nanoparticle structures to absorb EM radiation. Specifically, the complex may be designed to maximize the absorption of the electromagnetic radiation emitted from the sun. Further, each complex may absorb EM radiation over a specific range of wavelengths.

In one or more embodiments, the complex may include metal nanoshells. A nanoshell is a substantially spherical dielectric core surrounded by a thin metallic shell. The plasmon resonance of a nanoshell may be determined by the size of the core relative to the thickness of the metallic shell. Nanoshells may be fabricated according to U.S. Pat. No. 6,685,986, hereby incorporated by reference in its entirety. The relative size of the dielectric core and metallic shell, as well as the optical properties of the core, shell, and medium, determines the plasmon resonance of a nanoshell. Accordingly, the overall size of the nanoshell is dependent on the

absorption wavelength desired. Metal nanoshells may be designed to absorb or scatter light throughout the visible and infrared regions of the electromagnetic spectrum. For example, a plasmon resonance in the near infrared region of the spectrum (700 nm-900 nm) may have a substantially spherical silica core having a diameter between 90 nm-175 nm and a gold metallic layer between 4 nm-35 nm.

A complex may also include other core-shell structures, for example, a metallic core with one or more dielectric and/or metallic layers using the same or different metals. For example, a complex may include a gold or silver nanoparticle, spherical or rod-like, coated with a dielectric layer and further coated with another gold or silver layer. A complex may also include other core-shell structures, for example hollow metallic shell nanoparticles and/or multi-layer shells.

In one or more embodiments, a complex may include a nanoshell encapsulated with a dielectric or rare earth element oxide. For example, gold nanoshells may be coated with an additional shell layer made from silica, titanium or europium oxide.

In one embodiment of the invention, the complexes may be aggregated or otherwise combined to create aggregates. In such cases, the resulting aggregates may include complexes of the same type or complexes of different types.

In one embodiment of the invention, complexes of different types may be combined as aggregates, in solution, or embedded on substrate. By combining various types of complexes, a broad range of the EM spectrum may be absorbed.

FIG. 1 is a schematic of a nanoshell coated with an additional rare earth element oxide in accordance with one or more embodiments of the invention. Typically, a gold nanoshell has a silica core **102** surrounded by a thin gold layer **104**. As stated previously, the size of the gold layer relative to the size of the core determines the plasmon resonance of the particle. According to one or more embodiments of the invention, a nanoshell may then be coated with a dielectric or rare earth layer **106**. The additional layer **106** may serve to preserve the resultant plasmon resonance and protect the particle from any temperature effects, for example, melting of the gold layer **104**.

FIG. 2 is a flow chart of a method of manufacturing the coated nanoshells in accordance with one or more embodiments of the invention. In ST **200**, nanoshells are manufactured according to known techniques. In the example of europium oxide, in ST **202**, 20 mL of a nanoshell solution may be mixed with 10 mL of 2.5M $(\text{NH}_4)_2\text{CO}$ and 20 mL of 0.1M of $\text{Eu}(\text{NO}_3)_3 \cdot x\text{H}_2\text{O}$ solutions in a glass container. In ST **204**, the mixture may be heated to boiling for 3-5 minutes under vigorous stirring. The time the mixture is heated may determine the thickness of the additional layer, and may also determine the number of nanoparticle aggregates in solution. The formation of nanostructure aggregates is known to create additional plasmon resonances at wavelengths higher than the individual nanostructure that may contribute to the energy absorbed by the nanostructure for heat generation. In ST **206**, the reaction may then be stopped by immersing the glass container in an ice bath. In ST **208**, the solution may then be cleaned by centrifugation, and then redispersed into the desired solvent. The additional layer may contribute to the solubility of the nanoparticles in different solvents. Solvents that may be used in one or more embodiments of the invention include, but are not limited to, water, ammonia, ethylene glycol, and glycerin.

In addition to europium, other examples of element oxides that may be used in the above recipe include, but are not limited to, erbium, samarium, praseodymium, and dys-

5

prosium. The additional layer is not limited to rare earth oxides. Any coating of the particle that may result in a higher melting point, better solubility in a particular solvent, better deposition onto a particular substrate, and/or control over the number of aggregates or plasmon resonance of the particle may be used. Examples of the other coatings that may be used in, but are not limited to silica, titanium dioxide, polymer-based coatings, additional layers formed by metals or metal alloys, and/or combinations of materials.

FIG. 3 is an absorbance spectrum of three nanoparticle structures that may be included in a complex in accordance with one or more embodiments disclosed herein. In FIG. 3, a gold nanoshell spectrum **308** may be engineered by selecting the core and shell dimensions to obtain a plasmon resonance peak at ~800 nm. FIG. 3 also includes a Eu_2O_3 -encapsulated gold nanoshell spectrum **310**, where the Eu_2O_3 -encapsulated gold nanoshell is manufactured using the same nanoshells from the nanoshell spectrum **308**. As may be seen in FIG. 3, there may be some particle aggregation in the addition of the europium oxide layer. However, the degree of particle aggregation may be controlled by varying the reaction time described above. FIG. 3 also includes a ~100 nm diameter spherical gold colloid spectrum **312** that may be used to absorb electromagnetic radiation in a different region of the electromagnetic spectrum. In the specific examples of FIG. 3, the Eu_2O_3 -encapsulated gold nanoshells may be mixed with the gold colloids to construct a complex that absorbs any EM radiation from 500 nm to greater than 1200 nm. The concentrations of the different nanoparticle structures may be manipulated to achieve the desired absorption of the complex.

X-ray photoelectron spectroscopy (XPS) and/or energy dispersive x-ray spectroscopy (EDS) measurements may be used to investigate the chemical composition and purity of the nanoparticle structures in the complex. For example, FIG. 4A shows an XPS spectrum in accordance with one or more embodiments of the invention. XPS measurements were acquired with a PHI Quantera X-ray photoelectron spectrometer. FIG. 4A shows the XPS spectra in different spectral regions corresponding to the elements of the nanoshell encapsulated with europium oxide. FIG. 4A shows the XPS spectra display the binding energies for Eu (3d 5/2) at 1130 eV **414**, Eu (2d 3/2) at 1160 eV **416**, Au (4f 7/2) at 83.6 eV **418**, and Au (4f 5/2) at 87.3 eV **420** of nanoshells encapsulated with europium oxide. For comparison, FIG. 4B shows an XPS spectrum of europium oxide colloids that may be manufactured according to methods known in the art. FIG. 4B shows the XPS spectra display the binding energies for Eu (3d 5/2) at 1130 eV **422** and Eu (2d 3/2) at 1160 eV **424** of europium oxide colloids.

Similar to above, in one or more embodiments of the invention, the complex may include solid metallic nanoparticles encapsulated with an additional layer as described above. For example, using the methods described above, solid metallic nanoparticles may be encapsulated using silica, titanium, europium, erbium, samarium, praseodymium, and dysprosium. Examples of solid metallic nanoparticles include, but are not limited to, spherical gold, silver, copper, or nickel nanoparticles or solid metallic nanorods. The specific metal may be chosen based on the plasmon resonance, or absorption, of the nanoparticle when encapsulated. The encapsulating elements may be chosen based on chemical compatibility, the encapsulating elements ability to increase the melting point of the encapsulated nanoparticle structure, and the collective plasmon resonance, or absorption, of a solution of the encapsulated

6

nanostructure, or the plasmon resonance of the collection of encapsulated nanostructures when deposited on a substrate.

In one or more embodiments, the complex may also include copper colloids. Copper colloids may be synthesized using a solution-phase chemical reduction method. For example, 50 mL of 0.4 M aqueous solution of L-ascorbic acid, 0.8M of Polyvinyl pyridine (PVP), and 0.01M of copper (II) nitride may be mixed and heated to 70 degree Celsius until the solution color changes from a blue-green color to a red color. The color change indicates the formation of copper nanoparticles. FIG. 5 is an experimental and theoretical spectrum in accordance with one or more embodiments of the invention. FIG. 5 includes an experimental absorption spectrum **526** of copper colloids in accordance with one or more embodiments of the invention. Therefore, copper colloids may be used to absorb electromagnetic radiation in the 550 nm to 900 nm range.

FIG. 5 also includes a theoretical absorption spectrum **528** calculated using Mie scattering theory. In one or more embodiments, Mie scattering theory may be used to theoretically determine the absorbance of one or more nanoparticle structures to calculate and predict the overall absorbance of the complex. Thus, the complex may be designed to maximize the absorbance of solar electromagnetic radiation.

Referring to FIG. 6, an EDS spectrum of copper colloids in accordance with one or more embodiments of the invention is shown. The EDS spectrum of the copper colloids confirms the existence copper atoms by the appearance peaks **630**. During the EDS measurements, the particles are deposited on a silicon substrate, as evidenced by the presence of the silicon peak **632**.

In one or more embodiments, the complex may include copper oxide nanoparticles. Copper oxide nanostructures may be synthesized by 20 mL aqueous solution of 62.5 mM $\text{Cu}(\text{NO}_3)_2$ being directly mixed with 12 mL NH_4OH under stirring. The mixture may be stirred vigorously at approximately 80° C. for 3 hours, then the temperature is reduced to 40° C. and the solution is stirred overnight. The solution color turns from blue to black color indicating the formation of copper oxide nanostructure. The copper oxide nanostructures may then be washed and re-suspended in water via centrifugation. FIG. 7 shows the absorption of copper oxide nanoparticles in accordance with one or more embodiments of the invention. The absorption of the copper oxide nanoparticles **734** may be used to absorb electromagnetic radiation in the region from ~900 nm to beyond 1200 nm.

In one or more embodiments of the invention, the complex may include branched nanostructures. One of ordinary skill in the art will appreciate that embodiments of the invention are not limited to strict gold branched structures. For example, silver nickel, copper, or platinum branched structures may also be used. FIG. 8 is a flow chart of the method of manufacturing gold branched structures in accordance with one or more embodiments of the invention. In ST **800**, an aqueous solution of 1% HAuCl_4 may be aged for two-three weeks. In ST **802**, a polyvinyl pyridine (PVP) solution may be prepared by dissolving 0.25 g in approximately 20 mL ethanol solution and resealed with water to a final volume of 50 mL. In ST **804**, 50 mL of the 1% HAuCl_4 and 50 mL of the PVP solution may be directly mixed with 50 mL aqueous solution of 0.4M L-ascorbic acid under stirring. The solution color may turn immediately in dark blue-black color which indicates the formation of a gold nanoflower or nano-coral. Then, in ST **806**, the Au nanostructures may then be washed and resuspended in water via centrifugation. In other words, the gold branched nanostruc-

tures may be synthesized through L-ascorbic acid reduction of aqueous chloroaurate ions at room temperature with addition of PVP as the capping agent. The capping polymer PVP may stabilize the gold branched nanostructures by preventing them from aggregating. In addition, the gold branched nanostructures may form a porous polymer-type matrix.

FIG. 9 shows the absorption of a solution of gold branched nanostructures in accordance with one or more embodiments of the invention. As can be seen in FIG. 9, the absorption spectrum **936** of the gold branched nanostructures is almost flat for a large spectral range, which may lead to considerably high photon absorption. The breadth of the spectrum **936** of the gold branched nanostructures may be due to the structural diversity of the gold branched nanostructures or, in other words, the collective effects of which may come as an average of individual branches of the gold branched/corals nanostructure.

FIG. 10 shows the EDS measurements of the gold branched nanostructures in accordance with one or more embodiments of the invention. The EDS measurements may be performed to investigate the chemical composition and purity of the gold branched nanostructures. In addition, the peaks **1038** in the EDS measurements of gold branched nanostructures confirm the presence Au atoms in the gold branched nanostructures.

FIG. 11 shows a Brunauer-Emmett-Teller (BET) surface area and pore size distribution analysis of branches in accordance with one or more embodiments of the invention. The BET surface area and pore size may be performed to characterize the branched nanostructures. FIG. 11A presents the nitrogen adsorption-desorption isotherms of a gold coral sample calcinated at 150° C. for 8 hours. The isotherms may exhibit a type IV isotherm with a N₂ hysteresis loops in desorption branch as shown. As shown in FIG. 11A, the isotherms may be relatively flat in the low-pressure region (P/P₀<0.7). Also, the adsorption and desorption isotherms may be completely superposed, a fact which may demonstrate that the adsorption of the samples mostly likely occurs in the pores. At the relative high pressure region, the isotherms may form a loop due to the capillarity agglomeration phenomena. FIG. 11B presents a bimodal pore size distribution, showing the first peak **1140** at the pore diameter of 2.9 nm and the second peak **1142** at 6.5 nm. FIG. 11C shows the BET plots of gold branched nanostructures in accordance with one or more embodiments of the invention. A value of 10.84 m²/g was calculated for the specific surface area of branches in this example by using a multipoint BET-equation.

In one or more embodiments of the invention, the gold branched nanostructures dispersed in water may increase the nucleation sites for boiling, absorb electromagnetic energy, decrease the bubble lifetime due to high surface temperature and high porosity, and increase the interfacial turbulence by the water gradient temperature and the Brownian motion of the particles. The efficiency of a gold branched complex solution may be high because it may allow the entire fluid to be involved in the boiling process.

As demonstrated in the above figures and text, in accordance with one or more embodiments of the invention, the complex may include a number of different specific nanostructures chosen to maximize the absorption of the complex in a desired region of the electromagnetic spectrum. In addition, the complex may be suspended in different solvents, for example water or ethylene glycol. Also, the complex may be deposited onto a surface according to known techniques. For example, a molecular or polymer

linker may be used to fix the complex to a surface, while allowing a solvent to be heated when exposed to the complex. The complex may also be embedded in a matrix or porous material. For example, the complex may be embedded in a polymer or porous matrix material formed to be inserted into a particular embodiment as described below. For example, the complex could be formed into a removable cartridge. As another example, a porous medium (e.g., fiberglass) may be embedded with the complex and placed in the interior of a vessel containing a fluid to be heated. The complex may also be formed into shapes in one or more embodiments described below in order to maximize the surface of the complex and, thus, maximize the absorption of EM radiation. In addition, the complex may be embedded in a packed column or coated onto rods inserted into one or more embodiments described below.

FIGS. 12A-12C show charts of the mass loss and temperature increase of different nanostructures that may be used in a complex in accordance with one or more embodiments of the invention. The results shown in FIGS. 12A-12C were performed to monitor the mass loss of an aqueous nanostructure solution for 10 minutes under sunlight (FIG. 12B) versus non-pulsed diode laser illumination at 808 nm (FIG. 12A). In FIG. 12A, the mass loss versus time of the laser illumination at 808 nm is shown for Eu₂O₃-coated nanoshells **1244**, non-coated gold nanoshells **1246**, and gold nanoparticles with a diameter of ~100 nm **1248**. Under laser exposure, as may be expected from the absorbance shown in FIG. 3, at 808 nm illumination, the coated and non-coated nanoshells exhibit a mass loss due to the absorbance of the incident electromagnetic radiation at 808 nm. In addition, as the absorbance is lower at 808 nm, the 100 nm diameter gold colloid exhibits little mass loss at 808 nm illumination. In FIG. 12A, the Au nanoparticles demonstrated a lower loss rate that was nearly the same as water because the laser wavelength was detuned from plasmon resonance frequency. The greatest mass loss was obtained by adding a layer around the gold nanoshells, where the particle absorption spectrum was approximately the same as the solar spectrum (see FIG. 3.)

In FIG. 12B, the mass loss as a function of time under exposure to the sun in accordance with one or more embodiments of the invention is shown. In FIG. 12B, the mass loss under sun exposure with an average power of 20 W is shown for Eu₂O₃-coated nanoshells **1250**, non-coated gold nanoshells **1252**, gold nanoparticles with a diameter of ~100 nm **1254**, and a water control **1256**. As in the previous example, the greatest mass loss may be obtained by adding a rare earth or dielectric layer around a nanoshell.

The resulting mass loss curves in FIGS. 12A and 12B show significant water evaporation rates for Eu₂O₃-coated gold nanoshells. The mass loss may be slightly greater under solar radiation because the particles were able to absorb light from a broader range of wavelengths. In addition, the collective effect of aggregates broadens the absorption spectrum of the oxide-coated nanoparticles, which may help to further amplify the heating effect and create local areas of high temperature, or local hot spots. Aggregates may also allow a significant increase in boiling rates due to collective self organizing forces. The oxide layer may further enhance steam generation by increasing the surface area of the nanoparticle, thus providing more boiling nucleation sites per particle, while conserving the light-absorbing properties of nanostructure.

FIG. 12C shows the temperature increase versus time under the 808 nm laser exposure in accordance with one or more embodiments of the invention. In FIG. 12C, the

temperature increase under the 808 nm laser exposure is shown for Eu_2O_3 -coated nanoshells **1258**, non-coated gold nanoshells **1260**, gold nanoparticles with a diameter of ~100 nm **1262**, and a water control **1264**. As may be expected, the temperature of the solutions of the different nanostructures that may be included in the complex increases due to the absorption of the incident electromagnetic radiation of the specific nanostructure and the conversion of the absorbed electromagnetic radiation in to heat.

FIG. **13A** is a chart of the solar trapping efficiency in accordance with one or more embodiments of the invention. To quantify the energy trapping efficiency of the complex, steam is generated in a flask and throttled through a symmetric convergent-divergent nozzle. The steam is then cooled and collected into an ice bath maintained at 0° C. The nozzle serves to isolate the high pressure in the boiler from the low pressure in the ice bath and may stabilize the steam flow. Accordingly, the steam is allowed to maintain a steady dynamic state for data acquisition purposes. In FIG. **13A**, the solar energy capture efficiency (η) of water (i) and Eu_2O_3 -coated nanoshells (ii) and gold branched (ii) nanostructures is shown. The resulting thermal efficiency of steam formation may be estimated at 80% for the coated nanoshell complex and 95% for a gold branched complex. By comparison, water has approximately 10% efficiency under the same conditions.

In one or more embodiments of the invention, the concentration of the complex may be modified to maximize the efficiency of the system. For example, in the case where the complex is in solution, the concentration of the different nanostructures that make up the complex for absorbing EM radiation may be modified to optimize the absorption and, thus, optimize the overall efficiency of the system. In the case where the complex is deposited on a surface, the surface coverage may be modified accordingly.

In FIG. **13B**, the steam generation efficiency versus gold nanoshell concentration for solar and electrical heating in accordance with one or more embodiments of the invention is shown. The results show an enhancement in efficiency for both electrical **1366** and solar **1368** heating sources, confirming that the bubble nucleation rate increases with the concentration of complex. At high concentrations, the complex is likely to form small aggregates with small inter-structure gaps. These gaps may create "hot spots", where the intensity of the electric field may be greatly enhanced, causing an increase in temperature of the surrounding water. The absorption enhancement under electrical energy **1366** is not as dramatic as that under solar power **1368** because the solar spectrum includes energetic photons in the NIR, visible and UV that are not present in the electric heater spectrum. At the higher concentrations, the steam generation efficiency begins to stabilize, indicating a saturation behavior. This may result from a shielding effect by the particles at the outermost regions of the flask, which may serve as a virtual blackbody around the particles in the bulk solution.

FIG. **14** shows a power generation system **1400** for creating vapor for electricity generation in accordance with one or more embodiments of the invention. The power generation system **1400** includes a heat generation system **1410**, a fluid heating system **1420**, a generation system **1430**, a condenser **1440**, and, optionally, a fluid supply system **1450**. The heat generation system **1410** includes, optionally, an EM radiation source **1414** and an EM radiation concentrator **1412**. The fluid heating system **1420** includes a vessel **1422** and, optionally, a temperature gauge **1424** and a superheater **1426**. The generating system **1430** includes a vapor-driven turbine **1432** and a generator **1434**. The

optional fluid supply system **1450** includes a fluid source **1452**, a pump **1454**, and a fluid treatment facility **1456**. Each of these components is described with respect FIG. **1400** below. One of ordinary skill in the art will appreciate that embodiments of the invention are not limited to the configuration shown in FIG. **1400**.

For each component shown in FIG. **14**, as well as any other component implied and/or described but not shown in FIG. **14**, may be configured to receive material from one component (i.e., an upstream component) of the power generation system **1400** and send material (either the same as the material received or material that has been altered in some way (e.g., vapor to fluid)) to another component (i.e., a downstream component) of the power generation system **1400**. In all cases, the material received from the upstream component may be delivered through a series of pipes, pumps, valves, and/or other devices to control factors associated with the material received such as the flow rate, temperature, and pressure of the material received as it enters the component. Further, the fluid and/or vapor may be delivered to the downstream component using a different series of pipes, pumps, valves, and/or other devices to control factors associated with the material sent such as the flow rate, temperature, and pressure of the material sent as it leaves the component.

In one or more embodiments of the invention, the heat generation system **1410** of the power generation system **1400** is configured to provide EM radiation. The heat generation system **1410** may be ambient light, as produced by the sun or one or more light bulbs in a room. Optionally, in one or more embodiments of the invention, the EM radiation source **1414** is any other source capable of emitting EM radiation having one or a range of wavelengths. The EM radiation source **1414** may be a stream of flue gas derived from a combustion process using a fossil fuel, including but not limited to coal, fuel oil, natural gas, gasoline, and propane. In one or more embodiments of the invention, the stream of flue gas is created during the production of heat and/or electric power using a boiler to heat water using one or more fossil fuels. The stream of flue gas may also be created during some other industrial process, including but not limited to chemical production, petroleum refining, and steel manufacturing. The stream of flue gas may be conditioned before being received by the heat generation system **1410**. For example, a chemical may be added to the stream of flue gas, or the temperature of the stream of flue gas may be regulated in some way. Conditioning the stream of flue gas may be performed using a separate system designed for such a purpose.

In one or more embodiments of the invention, the EM radiation source **1414** is any other natural and/or manmade source capable of emitting one or more wavelengths of energy. The EM radiation source **1414** may also be a suitable combination of sources of EM radiation, whether emitting energy using the same wavelengths or different wavelengths.

Optionally, in one or more embodiments of the invention, the EM radiation concentrator **1412** is a device used to intensify the energy emitted by the EM radiation source **1414**. Examples of an EM radiation concentrator **1412** include, but are not limited to, one or more lenses (e.g., Fresnel lens, biconvex, negative meniscus, simple lenses, complex lenses), a parabolic trough, black paint, one or more disks, an array of multiple elements (e.g., lenses, disks), or any suitable combination thereof. The EM radiation concentrator **1412** may be used to increase the rate at which the EM radiation is absorbed by the complex.

11

In one or more embodiments of the invention, the fluid heating system **1420** of the power generation system **1400** is configured to transform (i.e., convert) the fluid into vapor. Specifically, the vessel **1422** of the fluid heating system **1420** may include the complex used to heat the fluid. The vessel **1422** may include a liquid solution (or some other material, liquid or otherwise, such as ethylene glycol or glycine) that includes the complex, be coated on one or more inside surfaces with a coating of the complex, be coated on one or more outside surfaces with a coating of the complex, include a porous matrix into which the complex is embedded, include a packed column that includes packed, therein, a substrate on which the complex is attached, include rods or similar objects coated with the complex and submerged in the fluid and/or liquid solution, be constructed of a material that includes the complex, or any combination thereof. The vessel **1422** may also be adapted to facilitate one or more EM radiation concentrator's **1412**, as described above.

The vessel **1422** may be of any size, material, shape, color, degree of translucence/transparency, or any other characteristic suitable for the operating temperatures and pressures to produce the amount and type of vapor required to generate the electricity. For example, the vessel **1422** may be a large, stainless steel cylindrical tank holding a quantity of solution that includes the complex and with a number of lenses (acting as EM radiation concentrators) along the lid and upper walls. In such a case, the solution may include the fluid being used to be transformed into vapor. Further, in such a case, the fluid includes properties such that the complex remains in the solution when a filtering system (described below) is used. Alternatively, the vessel **1422** may be a translucent pipe with the interior surfaces coated with a substrate of the complex, where the pipe is positioned at the focal point of a parabolic trough (acting as an EM radiation concentrator) made of reflective metal.

Optionally, in one or more embodiments of the invention, the vessel **1422** includes one or more temperature gauges **1424** to measure a temperature at different points inside the vessel **1422**. For example, a temperature gauge **1424** may be placed at the point in the vessel **1422** where the vapor exits the vessel **1422**. Such temperature gauge **1424** may be operatively connected to a control system (not shown) used to control the amount and/or quality of vapor produced for generating electric power. In one or more embodiments of the invention, the vessel **1422** may be pressurized where the pressure is read and/or controlled using a pressure gauge (not shown). Those skilled in the art will appreciate one or more control systems used to generate steam for generating electricity may involve a number of devices, including but not limited to the temperature gauge(s) **1424**, pressure gauges, pumps (e.g., pump **1454**), fans, and valves, controlled (manually and/or automatically) according to a number of protocols and operating procedures.

Optionally, in one or more embodiments of the invention, the vessel **1422** may also include a filtering system (not shown) located inside the vessel **1422** to capture impurities in the fluid that are not converted to vapor with the fluid. The filtering system may vary, depending on a number of factors, including but not limited to the configuration of the vessel **1422**, the purity requirements of the vapor. The filtering system may be integrated with a control system. For example, the filtering system may operate within a temperature range measured by one or more temperature gauges **1424**.

Optionally, in one or more embodiments of the invention, the fluid heating system **1420** includes a superheater **1426**. The superheater **1426** may be used to increase the tempera-

12

ture of the vapor to a level required by the vapor-driven turbine **1432**. The superheater **1426** and similar devices used to process the vapor so that the characteristics of the vapor are within the operating requirements of the vapor-driven turbine **1432** are known in the art and will not be described further herein.

In one or more embodiments of the invention, the generating system **1430** of the power generation system **1400** is configured to use the vapor to generate electricity. The vapor-driven turbine **1432** may include one or more chambers (e.g., sets of turbine blades) operating at one or more different pressures. The vapor-driven turbine **1432** may also include different sizes of turbine blades. In one or more embodiments of the invention, the vapor-driven turbine **1432** is sized in accordance with the specifications of the generator **1434**. Those skilled in the art will appreciate that the vapor-driven turbine **1432** of the generating system **1430** may be any type of turbine, now known or to be discovered, adapted to receive vapor, which turns one or more blades of the turbine.

In one or more embodiments of the invention, the generator **1434** of the generating system **1430** rotates in response to the turning of the turbine blades of the vapor-driven turbine **1432** to create electricity. The generator **1434** may include a rotor that rotates inside a stator, inducing electromagnetic current in the stator. The energy created by the vapor-driven turbine **1432** may, either directly or indirectly, be used to rotate the rotor of the generator **1434**. For example, the rotor of the generator **1434** may be directly connected to the vapor-driven turbine **1432** by a shaft. The energy created by the vapor-driven turbine **1432** may also be stored, for example in a compressor, where the stored energy is later used to indirectly rotate the rotor of the generator **1434**. The generator **1434** may also some other source of energy, including but not limited to a battery and a compressor. The generator **1434** may be capable of generating any amount of power, from a few kilowatts (or less) to several hundred megawatts (or more). Those skilled in the art will appreciate that the generator **1434** may be any type of generator, now known or to be discovered, adapted to create electromagnetic current or some other form of energy using the energy transferred from the vapor-driven turbine **1432**.

In one or more embodiments of the invention, the condenser **1440** of the power generation system **1400** is configured to condense the vapor received from the generating system **1430** to fluid. The fluid condensed by the condenser **1440** may be the same as the fluid received by the fluid heating system **1420** described above. The condenser **1440** may use air, water, or any other suitable material/medium to cool the vapor. The condenser **1440** may also operate under a particular pressure, such as under a vacuum. Those skilled in the art will appreciate that the condenser **1440** may be any type of condenser, now known or to be discovered, adapted to liquefy a vapor.

Optionally, in one or more embodiments of the invention, the fluid supply system **1450** of the power generation system **1400** is configured to supply fluid to the fluid heating system **1420**. The fluid source **1452** of the fluid supply system **1450** may be any source of fluid. For example, the fluid source **1452** may include, but is not limited to, the condenser **1440**, a pond, a lake, a chemical mixing tank, recycled fluid from a closed-loop system (described below), some other suitable source, or any combination thereof. For example, the condenser **1440** may be a primary source of fluid to the fluid heating system **1420**, and a lake, fed by a pump, may be used as an initial source of the fluid (as when the fluid heating

13

system **1420** is drained for maintenance) and as a secondary source of the fluid (as when incremental amounts of fluid are needed during operation of the power generation system **1400** to make up for losses in the fluid heating system **1420**). The flow of fluid to and/or from the fluid source **1452** may be controlled by one or more pumps **1454**, which may operate manually or automatically (as with a control system, described above). Each pump **1454** may operate using a variable speed motor or a fixed speed motor. The flow of fluid to and/or from the fluid source **1452** may also be controlled by gravity, pressure differential, some other suitable mechanism, or any combination thereof.

In one or more embodiments of the invention, the fluid treatment facility **1456** is used to treat the fluid received by the fluid supply system **1450** so that the fluid includes characteristics (e.g., pH, mixture of elements and/or compounds, temperature) required by the fluid heating system **1420**. The fluid treatment facility **1456** may include any equipment necessary to treat the fluid, including but not limited to a mixing vat, a centrifuge, a chemical separator, and a temperature-controlled holding tank.

FIG. **15** shows a flowchart for a method of creating vapor for generating electricity in accordance with one or more embodiments of the invention. While the various steps in this flowchart are presented and described sequentially, one of ordinary skill will appreciate that some or all of the steps may be executed in different orders, may be combined or omitted, and some or all of the steps may be executed in parallel. Further, in one or more of the embodiments of the invention, one or more of the steps described below may be omitted, repeated, and/or performed in a different order. In addition, a person of ordinary skill in the art will appreciate that additional steps, omitted in FIG. **15**, may be included in performing this method. Accordingly, the specific arrangement of steps shown in FIG. **15** should not be construed as limiting the scope of the invention.

Referring to FIG. **15**, in Step **1502**, a fluid is received in a vessel containing a complex. The fluid may be any liquid, such as water. The fluid may have impurities (e.g., other elements and/or compounds) that are not needed or wanted when the fluid is in vapor form. The vessel may be any container capable of holding a volume of the fluid. For example, the vessel may be a pipe, a chamber, or some other suitable container. In one or more embodiments of the invention, the vessel is adapted to maintain its characteristics (e.g., form, properties) under high temperatures for extended periods of time. The complex may be part of a solution inside the vessel, a coating on the outside of the vessel, a coating on the inside of the vessel, integrated as part of the material of which the vessel is made, integrated with the vessel in some other way, or any suitable combination thereof. The fluid may be received in the vessel using gravity, pressure differential, a pump, a valve, a regulator, some other device to control the flow of the fluid, or any suitable combination thereof.

Optionally, in Step **1504**, EM radiation sent by an EM radiation source (described above with respect to FIG. **14**) to the vessel is concentrated. In one or more embodiments of the invention, the EM radiation is concentrated using an EM radiation concentrator, as described above with respect to FIG. **14**. For example, the EM radiation may be concentrated using one or more lenses or a parabolic trough. In one or more embodiments of the invention, the EM radiation is concentrated merely by exposing the vessel to the EM radiation.

In Step **1506**, the EM radiation is applied to the complex. In one or more embodiments of the invention, the complex

14

absorbs the EM radiation to generate heat. The EM radiation may be applied to all or a portion of the complex contained in the vessel. The EM radiation may also be applied to an intermediary, which in turn applies the EM radiation (either directly or indirectly, as through convection) to the complex. A control system using, for example, one or more temperature gauges, may regulate the amount of EM radiation applied to the complex, thus controlling the amount of heat generated by the complex at a given point in time. Power required for any component in the control system may be supplied by any of a number of external sources (e.g., a battery, a photovoltaic solar array, alternating current power, direct current power) and/or from electric power generated by the generator, as in Step **1510** below.

In Step **1508**, the fluid is transformed into a vapor. In one or more embodiments of the invention, the heat generated by the complex is used to heat the fluid to any temperature at or beyond the boiling point of the fluid. In Step **1510**, the vapor is sent from the vessel to a turbine. In one or more embodiments of the invention, the vapor flows through the turbine, causing the turbine blades to turn. As the turbine blades turn, energy is transferred. In one or more embodiments of the invention, the turbine is coupled to a generator by a shaft. In such a case, the energy created by the spinning turbine is transferred to the generator through the shaft. As the generator turns, electric power may be produced. The energy created by the spinning turbine may also be transferred, directly or indirectly, to another device (e.g., a compressor, a battery) capable of generating electric power. The vapor may be sent from the vessel to the turbine using part of a control system, including but not limited to a fan (not shown). After completing Step **1510**, the process ends.

Optionally, after completing Step **1510**, the process proceeds to Step **1512**, where the vapor is condensed to a fluid. In one or more embodiments of the invention, a condenser is used to condense the vapor to a fluid. The fluid may be substantially the same fluid as the fluid described above with regard to Step **1502**. After completing Step **1512**, the process proceeds to Step **1502**. Optional Step **1512** is used as part of a recirculation or closed-loop system. In a closed-loop system, one or more other sources (e.g., a retention pond, a lake, a storage tank) of the fluid may be used in conjunction with the fluid condensed by the condenser. For example, a lake may be used to initially supply the fluid prior to starting the process described herein. Further, a retention pond may be used to supply incremental amounts of fluid during the process to make up for the incremental amounts of fluid that may be lost due to, for example, losses in the system. Using Step **1512** may increase the energy efficiency for creating steam to generate electric power.

Example 1—Closed-Loop System

Consider the following example, shown in FIG. **16**, which describes a process that produces steam used to generate electric power in accordance with one or more embodiments described above. Specifically, FIG. **16** illustrates a closed-loop system to produce the steam required to generate electric power. In one or more embodiments, the fluid supply **1602** is a lake or retention pond, where the fluid is water. A pump **1604** is used to move the water from the fluid supply **1602** to the vessel **1630**. In this example, the vessel **1630** may be a large tank, a boiler, or some similar container capable of withstanding the temperature, pressure, weight, and other parameters necessary to generate steam.

In this example, the vessel **1630** includes a concentrator **1610** in the form of a large lens integrated as part of the top

15

portion of the vessel **1630**. The vessel **1630** also includes a temperature gauge **1606** and a pressure gauge **1608**, which may be integrated with a control system (not shown). The water delivered to the vessel **1630** pools at the bottom portion **1632** of the vessel. In this example, the complex is mixed with the water at the bottom portion **1632** of the vessel. An EM radiation source (not shown), such as the sun, provides EM radiation to the concentrator **1610**, where the EM radiation is concentrated before entering the vessel **1630**. The concentrated EM radiation then contacts the water/complex solution at the bottom portion **1632** of the vessel. As the complex absorbs the EM radiation, heat is generated and transferred to the water in the solution. As the water is heated to a temperature at or above the boiling point of water, the water is transformed into steam and rises toward the top of the vessel **1630**.

The steam may leave the vessel **1630** through a pipe **1612**. The aforementioned control system may utilize a control valve **1614**, a fan, and/or some other device to control the flow of steam from the vessel **1630** to the turbine **1620**. Optionally, if the steam is not heated to a sufficiently high temperature, then a superheater **1616** may be used to increase the temperature of the steam to a point that is required to safely operate the turbine **1620**. Those skilled in the art will appreciate that the superheater **1616** may be any type of superheater, now known or to be discovered, adapted to increase the temperature of steam.

After the steam enters the turbine **1620**, consequently spinning the generator **1622** and creating electric power, the steam travels through a pipe **1624** to a condenser **1626**. In the condenser **1626**, the steam is condensed from steam to water, where it is returned to the fluid supply **1620** to repeat the process. The water may be drawn from the condenser **1626** to the fluid supply **1620** using a pump **1604**.

As discussed above, the vessel **1630** may take any of a number of forms. Further examples of various vessels are shown in FIGS. **17A** through **18B**. FIG. **17A**, a vessel **1704** in the form of a pipe is shown, along with a portion of a control system. Specifically, FIG. **17A** shows the fluid **1702** is sent through the tubular vessel **1704** using a pump **1712**. The flow of the fluid **1702** through the vessel **1704** may also be regulated by, for example, a valve **1708**. As the fluid reaches the front end of the vessel **1704**, a temperature gauge **1714** reads the temperature of the fluid at that point. The vessel in this example is partially surrounded by a parabolic trough **1706**, which is made of a reflective material used to direct the EM radiation sent by an EM radiation source (not shown) to the tubular vessel **1704**.

In this example, the vessel **1704** may be a pipe coated with a complex. Specifically, as shown in FIG. **17B**, the complex may be coated on the outside of the pipe **1722**, and the fluid **1720**, which flows inside the vessel, receives the heat generated by the complex at the inner wall of the pipe **1724**. Further examples of how the complex may be applied to the vessel are shown in FIGS. **18A** and **18B**. In FIG. **18A**, the complex **1804** is applied to the inside surface **1802** of the vessel. In this case, the complex **1804** is not applied evenly (i.e., non-uniformly), so that a greater amount of surface area of the complex **1804** comes in direct contact with the fluid as the fluid flows through the vessel. The greater amount of surface area allows for a greater transfer of heat from the complex **1804** to the fluid. The complex may also be applied evenly (i.e., uniformly) to the inside surface of the vessel. Alternatively, in FIG. **18B**, the complex **1810** is applied to the outer surface **1812** of the vessel as an even

16

coating. Those skilled in the art will appreciate that integrating the complex with the vessel may occur in any of a number of other ways.

Returning to FIG. **17A**, as the fluid **1702** travels through the vessel **1704**, the fluid **1702** changes to a vapor **1710**. As the vapor **1710** reaches the end of the vessel, a second temperature gauge **1716** may be used to measure the temperature of the steam at that point in time. A control system may regulate the speed of the motor controlling the pump **1712** based on, for example, the length of the vessel **1704**, the reading of the first and second temperature gauges **1714**, **1716**, and a sensor (not shown) to measure the intensity of the EM radiation.

Example 2—Waste Heat Recapture System

Consider the following example, shown in FIG. **19**, which describes a process that produces steam used to generate electric power in accordance with one or more embodiments described above. Specifically, FIG. **19** illustrates a closed-loop system that utilizes recaptured waste heat to produce the steam required to generate electric power. In one or more embodiments, the fluid source **1908** is a lake or retention pond, where the fluid is water. A pump **1910** is used to send the water from the fluid source **1908** to one end of a heat exchanger **1906**.

The heat exchanger **1906** may have two separate chambers that are adjacent to each other and allow the transfer of energy (e.g., heat) from a compound (e.g., gas, liquid) flowing through one of the chambers to a compound flowing through the other chamber. In the heat exchanger **1906**, the two compounds are separated by a solid wall so that the two compounds do not mix. In this case, the solid wall separating the two chambers may include a complex. For example, the solid wall may be made of a material in which the complex is integrated. Alternatively, a layer of complex may be adhered to the side of the solid that is exposed to the chamber in which the heated waste gas **1902** flows. In one embodiment of the invention, the solid wall separating the two chambers is designed to maximize the transfer of heat generated by the complex. For efficiency, the heat exchanger **1906** may be designed to maximize the surface area of the solid wall between the two compounds, while minimizing resistance to the flow of the compounds through both chambers of the heat exchanger **1906**. The performance of the heat exchanger **1906** may also be affected by the addition of fins or corrugations on one or both sides of the solid wall separating the chambers. The addition of fins or corrugations on one or both sides of the solid wall may increase surface area and/or channel flow of a compound to induce turbulence. A type of heat exchanger **1906** may be a plate heat exchanger, which is composed of multiple, thin, slightly-separated plates that have very large surface areas and flow passages in both chambers for heat transfer. Those skilled in the art will appreciate that the heat exchanger **1906** may be any other type of heat exchanger, now known or to be discovered, adapted to transfer energy from one chamber to another using two compounds.

In this example, the heat exchanger **1906** is transferring heat from a heated waste gas **1902** to the complex, and then heat is again transferred from the complex to the water sent by the fluid source **1908**. A source of the heated waste gas **1902** may include exhaust (e.g., flue gas) from a fossil fuel burned in a boiler or any other industrial process that creates vapor that is merely released or vented into air. The concept of recapturing heated waste gas, whether produced from the same or a different process, is known to those skilled in the

17

art. For example, the heat recovery steam generator (HRSG) is commonly used as part of a combined cycle power generation plant, where the HRSG uses flue gas created by a traditional natural gas-fired turbine to generate additional electrical power. In this example, the heated waste gas 1902 becomes exhaust 1904 after the heated waste gas 1902 exits the heat exchanger 1906, although the exhaust 1904 may be treated and/or used for some other purpose in the same or some other process.

Because of the heat transferred from the complex (heated by the waste gas 1902) to the water in the heat exchanger 1906, the water may be transformed to steam, which traverses through pipe 1914 from the heat exchanger 1906 to the turbine 1918. The rest of the process involving the optional superheater 1916, the turbine 1918, the shaft 1920, the generator 1922, the piping 1924 of the steam to the condenser 1926, the condenser 1926, and the piping 1928 from the condenser 1926 to the fluid source 1908 is substantially similar to the corresponding process involving the same or substantially similar components described above with respect to FIG. 17.

One or more embodiments of the invention increase the efficiency of an electricity generating system by creating steam using energy from an EM radiation source rather than using heat from burning a source, such as a fossil fuel (e.g., coal, fuel oil, natural gas, wood waste, black liquor). Consequently, embodiments of the invention may reduce or eliminate emissions (e.g., carbon dioxide, sulfur dioxide, mercury) that result from combusting fossil fuels to generate steam.

Further, embodiments of the invention may reduce the cost of building, operating, and maintaining a facility that generates steam for electricity production. Specifically, embodiments of the invention may reduce the number of pumps, fans, and other motor-driven equipment that require electricity to operate. Fuel handling and fuel processing facilities (e.g., coal handling, coal crushing/pulverization, wood chipping/pelletizing) may be reduced or eliminated using embodiments of the invention. Associated maintenance costs of such equipment may also be reduced or eliminated using embodiments of the invention. Further, embodiments of the invention may reduce the amount of chemicals and related equipment required to treat water used for steam to generate electricity.

While the invention has been described with respect to a limited number of embodiments, those skilled in the art, having benefit of this disclosure, will appreciate that other embodiments can be devised which do not depart from the scope of the invention as disclosed herein. Accordingly, the scope of the invention should be limited only by the attached claims.

What is claimed is:

1. A system to create vapor for generating electric power, the system comprising:

a vessel;

a fluid;

a complex;

wherein the vessel is configured to:

receive electromagnetic (EM) radiation from an EM radiation source;

apply the EM radiation to the complex, wherein the complex absorbs the EM radiation to generate heat; transform, using the heat generated by the complex, the fluid to vapor; and

send the vapor to a turbine; and

the turbine configured to receive, from the vessel, the vapor used to generate the electric power,

18

wherein the complex comprises:

a plurality of particles, and

an encapsulating dielectric layer configured to preserve a plasmon resonance of the complex,

wherein a first particle of the plurality of particles and a second particle of the plurality of particles are aggregated to form an aggregate.

2. The system of claim 1, wherein the fluid is water.

3. The system of claim 1, wherein a first type of complex and a second type of complex are present, wherein the complex is of the first type of complex.

4. The system of claim 3, wherein the first type of complex absorbs the EM radiation over a first range of wavelengths, wherein the second type of complex absorbs the EM radiation over a second range of wavelengths, and wherein the first range and the second range of wavelengths partially overlap.

5. The system of claim 1, wherein the system further comprises:

a concentrator, wherein the concentrator is a lens, wherein the vessel receives the EM radiation from the concentrator.

6. The system of claim 1, wherein the system further comprises:

a concentrator,

wherein the concentrator is a parabolic trough,

wherein the vessel receives the EM radiation from the parabolic trough, and

wherein the vessel comprises a section of pipe coated with the complex.

7. The system of claim 1, wherein the complex is used in a manner selected from at least one of a group consisting of being coated on an interior of the vessel, being coated on the exterior of the vessel, integrated with material from which the vessel is constructed, embedded in a porous matrix, embedded with fiberglass and placed in the interior of the vessel containing the fluid, embedded on a substrate that is in a packed column, coated on rods at least partially submerged in the fluid, and suspended in the fluid in the vessel.

8. The system of claim 1, wherein the system further comprises:

a control system comprising:

a pressure sensor configured to measure a pressure inside the vessel;

a valve that opens to release the vapor from the vessel when the pressure read by the pressure sensor is above a pressure threshold; and

a temperature sensor configured to measure a temperature inside the vessel, wherein the valve opens to release the vapor from the vessel when the temperature read by the temperature sensor is above a temperature threshold.

9. The system of claim 1, wherein the plurality of particles comprises one selected from a group consisting of copper nanoparticles, copper oxide nanoparticles, nanoshells, nanorods, carbon moieties, encapsulated nanoshells, encapsulated nanoparticles, and branched nanostructures.

10. The system of claim 1, wherein the vessel has a thermal efficiency of steam formation of 80% or greater.

11. A method to create vapor for generating electric power, the method comprising:

applying electromagnetic (EM) radiation to a vessel;

generating heat, by a complex disposed within the vessel, by absorbing the EM radiation;

transforming, using the heat generated by the complex, a fluid to a vapor; and

sending the vapor from the vessel to a turbine to generate the electric power,

wherein the complex comprises:

a plurality of particles, wherein each particle of the plurality of particles is one selected from a group 5 consisting of copper nanoparticles, copper oxide nanoparticles, nanoshells, nanorods, carbon moieties, encapsulated nanoshells, encapsulated nanoparticles, and branched nanostructures, and an encapsulating dielectric layer configured to preserve 10 a plasmon resonance of the complex,

wherein a first particle of the plurality of particles and a second particle of the plurality of particles are aggregated to form an aggregate.

12. The method of claim **11**, further comprising: 15 receiving the fluid in the vessel; and concentrating the EM radiation sent by an EM radiation source to the vessel,

wherein the fluid is received in the vessel from a condenser adapted to convert the vapor to the fluid after the 20 vapor flows through the turbine.
